In telecommunications, orthogonal frequency-division multiplexing (OFDM) is a type of digital transmission and a method of encoding digital data on multiple carrier frequencies. OFDM has developed into a popular scheme for wideband digital communication, used in applications such as digital television and audio broadcasting, DSL internet access, wireless networks, power line networks, and 4G ...

RocketBroadband is the only one able to offer multi-carrier redundancy and multi-SIM solutions. By partnering with both AT&T and Verizon we are able to provide 4G LTE connections via one or both carriers. With a multi-carrier connection, you gain some powerful advantages that you aren't able to get with a single-carrier connection.

Multicarrier modulation, MCM is a technique for transmitting data by sending the data over multiple carriers which are normally close spaced. Multicarrier modulation has several advantages including resilience to interference, resilience to narrow band fading and multipath effects. As a result, multicarrier modulation techniques are widely used for data transmission as it is able to provide an effective signal waveform which is spectrally efficient and resilient to the real world environment.

Multi-Carrier FDM. Each carrier is modulated with digital data. Using many carriers with error correction techniques improves the reliability of the communication link. If a few of the carriers get damaged, the link still works. ADSL Broadband Internet. Asymmetric Digital Subscriber Line (ADSL) uses a simple form of Frequency Division Multiplexing.
